Note Every image you produce is in a separate file. Even when you save a new document as a copy of an existing one, you're creating a new document. So if you start with an image and then save it as a copy—or a new document based on it—it's not a copy in the image-editing sense. At any rate, the following sections describe how to get started with Photoshop using the Getting to Know Photoshop dialog box. The next section details how to add a layer. # Creating a New Document in Photoshop Photoshop is loaded with tools and settings. For starters, you use a layer-based system. This means that you'll need a layer to work on a photo. You place that layer on top of other layers using a layer mask, as described on Layer Masks. Photoshop also lets you create a new document from scratch. You need a _blank_ layer to work on it, but you can use anything as a background. For example, your document may look like this: So far, so good. But how do you create a blank layer? If you create a new blank document, Photoshop creates a background for you. (If you try to create a background using nothing but a layer mask, you'll see a message letting you know you're in luck—Photoshop has created a background automatically for you. You can see a sample here, named _

Q: What is the relationship between sets and subsets? I've just started thinking about the concept of a set and a subset, and I want to make sure I'm understanding it correctly. For example, a set would be something like $\{1,2,3,4,5\}$, and a subset would be $\{2,4\}$. Now, in programming, how do these things relate to each other? I know I can write a function that takes any type of set as an argument and returns a subset. This function would simply output a sub-array of the input set. For example, $\{2,4,6,8,10\}$ would output $\{2,4\}$. I'm not sure about the reverse. I'm imagining creating a function that takes $\{2,4\}$ as an argument. What does this mean and what would this function output? $\{2,4,6,8,10\}$? I'm sorry for this basic question, but it really interests me as I'm about to start studying set theory.

A: A subset is a set with two additional properties: The elements of the subset are contained in the set that contains it. The elements of the subset are also elements of the first set. In practice, this means that every element in the subset must be a value in the first set. I can't see why you're bothered by this idea - in fact, it's the usual way to think about sets: there's a set, and a subset is just a subset of that set. For example, it's perfectly acceptable to say that the subset $S = \{\{1,2,3\}, \{2,3,4,5\}\}$ is a subset of $A = \{1,2,3,4,5\}$. In this case, the first property is obviously satisfied (it's true of every element in the subset: every element is a set of three numbers), and the second property is satisfied because every element of S is also an element of A . If you want a set with only the second property, you can say that the set $S' = \{\{2,4\}\}$ is a subset of A . S' is obviously

The present invention relates to a memory device, and more particularly to a scheme for controlling a refresh mode for a memory device. A typical memory device has a refresh (or refresh operation) operation for maintaining memory cells in an operable state. This refresh operation is described, for example, in a Refreshing Memory Architectures, White Paper, Micron Technology, Inc., 2000. According to this paper, a memory cell is divided into a memory cell array section and a refresh circuit section. The refresh circuit section is mounted on a chip in addition to the memory cell array section. The memory device controls the operation of the memory cell array section and the refresh circuit section in response to an external command. The external command instructs the memory device to perform the refresh operation or not. When the memory device performs the refresh operation, the memory device will not be responsive to the external command and input/output data. As a result, the memory device is under a standby state in which a refreshing operation is performed. When the memory device starts the refresh operation, it is impossible to apply a pre-computed amount of time to conduct the refreshing operation. Namely, the duration of the refreshing operation is not constant. When the memory device performs the refresh operation, it may be impossible to use the memory device as a system. Consequently, a pre-computed amount of time for the refreshing operation is generally preset. In this case, the memory device will be under a standby state for a predetermined pre-computed amount of time. This is because the memory device will be disabled while performing the refreshing operation and cannot be used as a system. In order to shorten the duration of the refreshing operation, the memory device may perform a refresh operation while the memory device is in an active state. When this operation is performed, it is impossible to apply a pre-computed amount of time to the refreshing operation. Accordingly, the memory device will be disabled for the pre-computed amount of time. In the case of the above-described memory device, a signal (or control signal) for instructing the memory device to perform a refresh operation is inputted to the memory device through an external terminal. The inputted signal is used for controlling the memory device, the memory device will be in a standby state when the memory device performs the refresh operation. A refresh period for the memory device is determined in accordance with the pre-computed amount of time. Since the inputted signal is used to control the memory device,
